THE COMMISSIONER OF PATENTS AND TRADEMARKS
Washington, DC 20231

Attorney Docket: 1391P

PATENT

Sir:

Transmitted herewith for filing is the Patent Application of

Inventor(s): **David B. Kirk**

For: **METHOD AND SYSTEM FOR PROVIDING A COMMAND STREAM IN A COMPUTER SYSTEM**

Enclosed with the Patent Application are:

- ☒ Six (6) sheets of Informal Drawings
☒ Declaration and Power of Attorney
☒ Assignment and Recordation Form
☒ Small Entity Status Declaration
☐ A certified copy of a _____ application
☒ Self Addressed, Stamped Postcard

The filing fee has been calculated as shown below:

(Col. 1) (Col. 2)

FOR:	NO. FILED		NO. EXTRA
BASIC FEE			
TOTAL CLAIMS	28 - 20	=	8
INDEP. CLAIMS	3 - 3	=	0
_ MULTIPLE DEPENDENT CLAIM PRESENTED			

*If the difference in Col. 1 is less than "0", enter "0" in Col. 2

☒ Please find enclosed Check No. 11949 in the amount of **\$452.00** for payment of application filing fees. A duplicate of this sheet is attached.

Kirk

Serial No.:

Filed: **Herewith**

For: **METHOD AND SYSTEM FOR PROVIDING A COMMAND STREAM IN A COMPUTER SYSTEM**

**DECLARATION CLAIMING SMALL ENTITY
STATUS UNDER 37 CFR 1.9(f) and 1.27(c)
SMALL BUSINESS CONCERN**

I hereby declare that I am

- ☐ the owner of the small business concern identified below:
☒ an official of the small business concern empowered to act on behalf of the concern identified below:

NAME OF CONCERN
ADDRESS OF CONCERN

nVidia
3535 Monroe Street
Santa Clara, California 95051

I hereby declare that the above identified small business concern qualifies as a small business concern as defined in 13 CFR 121.3-18, and reproduced in 37 CFR 1.9(d), for purposes of paying reduced fees under section 41(a) and (b) of Title 35, United States Code, in that the number of employees of the concern, including those of its affiliates, does not exceed 500 persons. For purposes of this statement, (1) the number of employees of the business concern is the average over the previous fiscal year of the concern of the persons employed on a full-time, part-time or temporary basis during each of the pay periods of the fiscal years, and (2) concerns are affiliates of each other when either, directly or indirectly, one concern controls or has the power to control the other, or a third party or parties controls or has the power to control both.

I hereby declare that rights under contract or law have been conveyed to and remain with the small business concern identified above with regard to the invention entitled **METHOD AND SYSTEM FOR PROVIDING A COMMAND STREAM IN A COMPUTER SYSTEM** by inventor(s) David B. Kirk, described in the application filed herewith.

The rights held by the above identified small business concern are not exclusive, each individual, concern or organization having rights to the invention is listed below* and no rights to the invention are held by any person, other than the inventor, who could not qualify as a small business concern under 37 CFR 1.9(d) or by any concern which would not qualify as a small business concern under 37 CFR 1.9(d) or a nonprofit organization under 37 CFR 1.9(e).

*NOTE: Separate verified statements are required from each named person, concern or organization having rights to the invention averring to their status as small entities. (37 CFR 1.27)

I acknowledge the duty to file, in this application or patent, notification of any change in status resulting in loss of entitlement to small entity status prior to paying, or at the time of paying, the earliest of the issue fee or any maintenance fee due after the date on which status as a small entity is no longer appropriate. (37 CFR 1.28(b))

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application, any patent issuing thereon, or any patent to which this declaration is directed.

Palo Alto, California 94303

METHOD AND SYSTEM FOR PROVIDING A COMMAND STREAM IN A COMPUTER SYSTEM

FIELD OF THE INVENTION

The present invention relates generally to a computer system and more particularly to a method and system for efficiently providing a command stream in a computer system.

BACKGROUND OF THE INVENTION

The constant emphasis in the design of computer systems has been to make such systems faster and able to handle larger amounts of information so that they may accomplish more work in less time. The ability of computers to do more work in less time is also enhanced by their ability to do more different kinds of work. For example, computers have become more useful in various applications with the advent of computer graphics displays which allow the presentation of numbers and text with pictures and graphs enhancing the meanings of the numbers and text. It has become the belief of a great number of people in the computer industry that a graphical output should be present on almost all computer systems.

In a typical computer system, a graphics controller sends video signals to monitors and also controls a frame buffer memory system. Data representing, for example, fonts are written into a frame buffer associated with the computer system. The graphics controller typically extracts the characters of the font to scan them onto a computer display or monitor.

A first conventional system for providing for a command stream for rendering data into the frame buffer on system memory requires that the command be downloaded directly from a central processing unit (CPU) via the graphics controller. In such an I/O buffer based system, a storage element, commonly referred to as first in first out (FIFO) buffer, within the graphics

controller is utilized to provide the data from the CPU to the graphics engine. There are two problems with this implementation. First, the FIFO buffer can be filled to varying degrees depending upon the relative speeds of the graphics engine and the CPU. If the graphics engine is relatively fast compared to the CPU, then the graphics engine is waiting for data from the CPU. This will adversely affect the overall system performance. If on the other hand the CPU is faster than the graphics engine, the FIFO may become full and then the CPU must either poll the graphics engine or the graphics engine must interrupt the CPU operation periodically. Accordingly, this type of system utilizes a considerable amount of processing power or overhead to perform these tasks.

In a multiprocessing environment, the interrupt is not utilized because there would be no effective way of determining the status of the processors when the interrupt takes place. Accordingly, in a multiprocessing environment, the typical method for utilizing the above-identified system is for the CPU to poll the graphics engine. Therefore, in a typical multiprocessing environment, if the FIFO buffer overflows, the graphics engine will send the command stream to a buffer within the graphics controller. The system will shut down because this is a failure mode. Thereafter, the system is rebooted or restarted based on normal operating conditions.

In a second conventional system, hereinafter referred to as a direct memory access (DMA) buffer system, a CPU accesses the system memory. That system memory in turn can be accessed by the graphics controller. A FIFO buffer is within the system memory which retains the command stream. This command stream can then be obtained by the graphics controller. The advantage of the DMA buffer system over the first conventional system is that

the graphics controller polls the system memory asynchronously from the CPU, and since the system memory is larger, there is less chance that the memory FIFO can become full.

However, as is also seen, the problem is that if the FIFO buffer is double-buffered, it is divided in half, based on both the CPU and the graphics controller having concurrent access to the FIFO buffer. Accordingly, an inherent problem with the second conventional system is that the size of the system memory buffer is effectively reduced by fifty percent (50%), thereby degrading the overall performance of the system. In addition, there is still significant overhead associated with CPU management of the FIFO buffer. For example, if the FIFO is a circular buffer, the CPU must still ensure that the write pointer does not overrun the read pointer and that the write pointer does not overrun the end of the buffer. In addition, the CPU must also ensure that the FIFO is not full.

Accordingly, what is needed is a system that provides a command stream more efficiently in a computer system. The system must be efficient, easily implemented and a cost-effective alternative to existing systems. The present invention solves such needs.

SUMMARY OF THE INVENTION

A system and method for providing a command stream on a chip or in a computer system is disclosed. The system comprises a central processing unit (CPU), a controller coupled to the CPU and a memory coupled to the controller. The controller manages the memory. The system and method also includes a storage element coupled to the memory, the storage element being accessible by the CPU via the controller.

The system and method in accordance with the present invention allows the controller to receive commands from the CPU and to manage the storage element, typically a first in first

out (FIFO) buffer, and incorporates the storage element as part of the memory. In so doing, the system performance is significantly improved by providing a virtual FIFO buffer such that the CPU sees a FIFO buffer with a size equal to the size of the memory. The bandwidth of the bus between the controller and the memory is typically greater than that of the system bus. Hence the performance of the overall system is significantly improved. In addition, since the controller is the only device that has access to the memory, the bandwidth of the bus associated therewith is not divided between two devices. Further, since the controller is managing the storage element, the overhead considerations that related to managing the read and write pointers of the storage element by the CPU are eliminated. Finally, a technique in accordance with the present invention is provided such that the controller determines whether the storage element must be emptied, rather than requiring the CPU to perform this function. Through these features, a command stream can be provided efficiently on a chip or in a computer system.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a block diagram of a conventional computer system.

Figure 2 illustrates a first conventional system for providing a command stream in a computer system.

Figure 3 illustrates a second conventional system for providing a command stream in a computer system.

Figure 3A illustrates an example of a conventional circular FIFO buffer.

Figure 4 is a simple block diagram illustrating a system 300 in accordance with the

present invention.

Figure 5 is a flow chart illustrating a process for eliminating the need for the CPU to determine if the FIFO buffer is full in accordance with the present invention.

5 DETAILED DESCRIPTION

The present invention relates generally to a computer system and more particularly to providing a command stream for rendering data in a computer system in an efficient manner. The following description is presented to enable one of ordinary skill in the art to make and use the invention and is provided in the context of a patent application and its requirements. Various modifications to the preferred embodiment and the generic principles and features described herein will be readily apparent to those skilled in the art. Thus, the present invention is not intended to be limited to the embodiment shown, but is to be accorded the widest scope consistent with the principles and features described herein.

Figure 1 is a block diagram of a conventional computer system. As is seen, the computer system 10 includes a CPU 12. In this embodiment, the CPU is coupled to a bridge 14, which is coupled to a bus 16 and a system memory 18. The bus 16 in a preferred embodiment is an AGP or PCI bus, which allows for signals to be sent thereon to I/O device 20, I/O device 22, graphics controller 24 and frame buffer 26. As is seen, the graphics controller 24 controls a frame buffer 26 and also sends video information (generally RGB) via a digital analog converter (DAC) 27 to a monitor 28.

It should be understood that although the elements of the computer system 10 are shown as discrete components, they can be combined in a variety of fashions and still be within

the spirit and scope of the present invention. For example, the bus 16 could be merged into the system, so that there is no actual system bus between the various components, but in fact the various components would communicate directly. In addition, the graphics controller 24, CPU 12, frame buffer 26, system memory 18 and I/O devices 20 and 22 could be integrated in any fashion and that combination would be within the spirit and scope of the present invention.

The following discussion will describe two conventional techniques for providing a command stream into a memory of a computer system. These conventional techniques will be described in the context of data being rendered into the frame buffer. However, one of ordinary skill in the art would readily recognize that the data could be rendered into any memory device within the computer system. For example the system memory could be utilized in this fashion.

Figure 2 illustrates a first conventional system 100 for providing a command stream in a computer system. In this system 100, the CPU 12' directly accesses a FIFO buffer 106 within the graphics controller 24' and the FIFO buffer 106 provides that data to a graphics engine 102. Typically, the FIFO buffer 106 is a circular FIFO buffer. As has also been above-explained, the CPU will have to either poll the graphics engine 102 to ensure that the FIFO buffer 106 is not full, or the graphics engine 102 will interrupt the CPU periodically to ensure that the FIFO buffer 106 is not overflowed. As has been above mentioned, both of these alternatives adversely affect system performance, and more particularly, in multiprocessing environments polling is the only option.

Figure 3 illustrates a second conventional system 200 for providing a command stream in a computer system. This system 200 provides some advantages over system 100 of Figure

2. In this DMA based system, the system memory 18' also includes a circular FIFO buffer 106'. Data is provided to the FIFO buffer 106' by the CPU 12''. The graphics controller 24'' also accesses the FIFO buffer 106' in system memory 18'. However, one problem with this approach is that the bandwidth of the system memory bus 107 is attenuated because both the graphics controller 24'' and the CPU 12'' must divide the memory interface 107 between them. This adversely affects the overall performance of the system. In addition, the CPU 12'' still has to manage the FIFO buffer 106' via the graphics controller 24'' which adds overhead to CPU 12''. To describe this problem with more particularity, please refer now to Figure 3A in conjunction with the accompanying description.

Figure 3A illustrates an example of a conventional circular FIFO buffer 106. The circular FIFO buffer 106 includes a plurality of data slots 109, a read pointer 120 and a write pointer 122. In a preferred embodiment, the FIFO buffer 106 will contain a maximum of 16 words of data. The read pointer 120 indicates where data is being read from and the write pointer 122 indicates where data is being written. The CPU 12'' (Figure 3) must manage the FIFO buffer 106 for two issues. The first issue is that write pointer 122 of FIFO buffer 106 cannot overrun the read pointer 120, and the write pointer 122 can not overrun the end of the FIFO buffer 106. The second issue is that the CPU 12'' (Figure 3) must ensure that the FIFO buffer 106 has not overflowed. It has been determined that almost twenty five percent (25%) of the instructions from a CPU 12'' are related to managing the FIFO buffer 106. Accordingly, it requires a significant amount of CPU 12'' overhead to manage the FIFO buffer 106.

Accordingly, there are two problems with the second conventional system for providing a command stream in a computer system. First, as shown in Figure 3, the system

memory bus 107 is attenuated because two devices (CPU 12" and the graphics controller 24") use the same system memory bus 107. Second, there is significant overhead associated with the CPU 12" managing the FIFO buffer 106'.

Accordingly, a system and method in accordance with the present invention addresses the above-mentioned problems by causing the graphics controller to manage the FIFO buffer and allowing the FIFO buffer to be part of the graphics memory. In so doing, system performance is significantly improved. First, the performance is improved since the bandwidth of the bus between the graphics engine and the graphics memory is typically greater than that of the system bus. In addition, the graphics engine is the only device that accesses that bus, so the bandwidth is not divided between two devices. Since the graphics engine is managing the FIFO buffer, the overhead considerations that related to managing the read and write pointers of the FIFO buffer by the CPU are eliminated. Finally, a technique in accordance with the present invention is provided to ensure that the CPU is not required to check if the FIFO buffer is full. To more particularly describe the present invention in more detail, refer now to the following description in conjunction with the accompanying figures.

Figure 4 is a block diagram illustrating a system 300 in accordance with the present invention as applied to a graphics system. The graphics engine 302 accepts a command stream through an interface 303 from the CPU 12". The graphics engine 302 in turn can utilize the graphics memory 26" as well as a storage element, such as a FIFO buffer 306, as the buffer for CPU purposes. Accordingly, the effective size of the entire buffer can be virtually the size of the graphics memory 26". Therefore, the CPU 12" will need to check whether the FIFO buffer 306 is full much less frequently than in the above conventional systems since the effective size

of the FIFO buffer is much larger. The graphics engine 302 manages the FIFO buffer 306 by checking for the end of the buffer and the buffer wrap around based upon the read and write pointers. This management can be further enhanced by using double and triple buffering techniques to ensure performance is optimal.

5 Accordingly, from the CPU's point of view, the interface 303 is the storage element. In fact, it is a storage element with a size equal to the size of graphics memory 26". In a preferred embodiment the storage element is a FIFO buffer 306 as shown in Figure 4 that, when full, is redirected to graphics memory 26". Data is read from the FIFO buffer 306 until empty, then from memory locations in the graphics memory 26", until graphics memory 26" is empty. The filling (writing) and emptying (reading) are asynchronous. Accordingly, the read/write pointers get switched to/from graphics memory 26" and FIFO buffer 306 in an arbitrary manner, however, the overall mechanism provides to CPU 12" the appearance of a FIFO buffer with a size equal to that of the graphics memory 26".

In another embodiment, a larger FIFO buffer can be provided, so that the larger FIFO buffer will rarely overflow and the runout path to graphics memory 26" can be much slower, saving implementation cost.

In yet another embodiment, the FIFO buffer 306 is a large buffer or buffers, part of which is paged out to the graphics memory 26" when it becomes full, and paged back into the FIFO buffer or buffers as needed. Another embodiment provides for double FIFO buffers, in
20 which the graphics engine 302 explicitly manages separate read and write buffers.

In a final embodiment, a triple FIFO buffers are utilized in which the graphics engine 302 explicitly manages separate read and write buffers and also manages an additional buffer

that is always free, to avoid deadlock or waiting when switching between the read and write buffers.

Accordingly, the CPU overhead associated with memory management is moved from CPU 12" to graphics engine 302. Typically, there is ten (10) times the bandwidth available on bus 305 as shown in Figure 4, than on system memory bus 107 as shown on Figure 3. In addition, since the graphics engine 302 is controlling the FIFO buffer 306, the read and write pointers can be managed thereby and a significant amount of overhead is removed from CPU 12". CPU 12" must still check to determine if FIFO buffer 306 has overflowed. However, since the FIFO buffer 306 is effectively larger, (kilobytes of data compared to sixteen (16) words of data), CPU 12" doesn't have to check nearly as often, thereby further reducing overhead.

It is desirable, however, to eliminate the overhead related to the CPU checking to determine if the FIFO buffer has overflowed. Accordingly, in a preferred embodiment as shown in Figure 5 there is a flow chart which illustrates a process for eliminating the need for the CPU to determine if the FIFO buffer has overflowed in accordance with the present invention. First, the time required to fill the FIFO buffer is calculated based upon the CPU speed and the size of the FIFO buffer, via step 402. Next, it is determined whether the used portion of the FIFO buffer is more than a predetermined amount based upon the time required to fill the FIFO buffer, via step 404. For example, the predetermined amount could be set at one half (1/2) of the size of the FIFO buffer. If the used portion is below the predetermined amount, then return to step 402. If the used space is above the predetermined amount, then the FIFO buffer is prevented from filling for a predetermined time period which is calculated so as

to empty the FIFO buffer, via step 406. Accordingly, a system and method in accordance with the present invention allows the graphics engine 302 to manage the FIFO buffer 306 and incorporates FIFO buffer 306 as part of graphics controller 24". In so doing, system performance is significantly improved.

5 The bandwidth of the bus 305 between graphics engine 302 and the graphics memory 26" as shown on Figure 4 is typically greater than that of system memory bus 107 as shown on Figure 3. Hence, the performance of the overall system is significantly improved. In addition, graphics engine 302 of Figure 4 is the only device that has access to bus 305 as shown on Figure 4; therefore the bandwidth is not divided between two (2) devices. Further since, as shown in Figure 4, graphics engine 302 is managing FIFO buffer 306, the overhead considerations related to managing the read and write pointers of the FIFO buffer by the CPU are eliminated. Finally, a technique in accordance with the present invention is provided to ensure that the CPU is not required to check if the FIFO buffer has overflowed. Through these features, a command stream can be provided efficiently in a computer system.

10 Although the present invention has been described in accordance with the embodiments shown, one of ordinary skill in the art will readily recognize that there could be variations to the embodiments and those variations would be within the spirit and scope of the present invention. Accordingly, many modifications may be made by one of ordinary skill in the art without departing from the spirit and scope of the appended claims.

CLAIMS

What is claimed is:

1 1. A controller chip comprising:
2 an engine for managing a memory and including an interface; and
3 a storage element coupled to the engine, the storage element being accessible by
4 a central processing unit (CPU), wherein the engine receives commands from the CPU via the
5 interface, manages the storage element and writes the commands into the memory.

1 2. The controller chip of claim 1 wherein the storage element comprises a first in
2 first out (FIFO) buffer.

1 3. The controller chip of claim 2 in which the FIFO buffer comprises a circular
2 FIFO buffer.

1 4. The controller chip of claim 2 in which the FIFO buffer comprises a double
2 buffer.

1 5. The controller chip of claim 2 in which the FIFO buffer comprises a triple
2 buffer.

1 6. The controller chip of claim 3 wherein the effective size of the FIFO buffer as

viewed by the CPU can be as large as the memory.

7. The controller chip of claim 2 which includes a checking mechanism for determining if the FIFO buffer needs to be emptied without utilizing the CPU.

8. The controller chip of claim 7 wherein the checking mechanism comprises:
means for calculating the time required to fill the FIFO buffer;
means for determining if the used memory of the FIFO buffer is below a predetermined amount based upon the time required to fill the FIFO buffer; and
means for preventing the FIFO buffer from filling if the used memory in the FIFO buffer is over the predetermined amount.

9. The controller chip of claim 1 wherein the controller chip comprises a graphics controller chip.

10. The controller chip of claim 9 wherein the engine comprises a graphics engine.

11. A system for providing a command stream in a computer system comprising:
a central processing unit (CPU);
a controller coupled to the CPU and including an interface;
a memory coupled to the controller, the memory being managed by the controller; and

6 a storage element coupled to the controller, the storage element being accessible
7 by the CPU, wherein the controller receives commands from the CPU via the interface,
8 manages the storage element and writes the commands into the memory.

1 12. The system of claim 11 wherein the storage element comprises a first in first
2 out (FIFO) buffer.

1 13. The system of claim 12 in which the FIFO buffer comprises a circular FIFO
2 buffer.

14. The system of claim 12 in which the FIFO buffer comprises a double buffer.

15. The system of claim 12 in which the FIFO buffer comprises a triple buffer.

16. The system of claim 12 in which the controller comprises a graphics controller.

1 17. The system of claim 12 wherein the effective size of the FIFO buffer can be as
2 large as the memory.

1 18. The system of claim 12 which includes a checking mechanism for determining
2 if the FIFO buffer needs to be emptied without utilizing the CPU.

1 19. The system of claim 18 wherein the checking mechanism comprises:
2 means for calculating the time required to fill the FIFO buffer;
3 means for determining if the FIFO buffer is below a predetermined amount
4 based upon the time required to fill the buffer; and
5 means for preventing the FIFO buffer from filling if the FIFO buffer is above
6 the predetermined amount.

1 20. A method for providing a command stream in a computer system, the computer
2 system including a central processing unit (CPU), a controller coupled to the CPU, a memory
3 coupled to the controller, the memory being managed by the controller; the method comprising
4 the steps of:
5

6 (a) providing a storage element within the controller; and

7 (b) allowing the storage element to be accessible by the CPU via an interface in the
8 graphics controller.

1 21. The method of claim 20 wherein the storage element comprises a FIFO buffer.

1 22. The method of claim 21 in which the FIFO buffer comprises a circular FIFO
2 buffer.

1 23. The method of claim 21 in which the FIFO buffer comprises a double buffer.

1 24. The method of claim 21 in which the FIFO buffer comprises a triple buffer.

1 25. The method of claim 21 in which the memory comprises a graphics memory.

1 26. The method of claim 21 wherein the effective size of the FIFO buffer as viewed
2 by the CPU can be as large as the memory.

1 27. The method of claim 21 which includes the step of (c) determining if the FIFO
2 buffer needs to be emptied without utilizing the CPU.

1 28. The method of claim 27 wherein the determining step (c) further comprises:

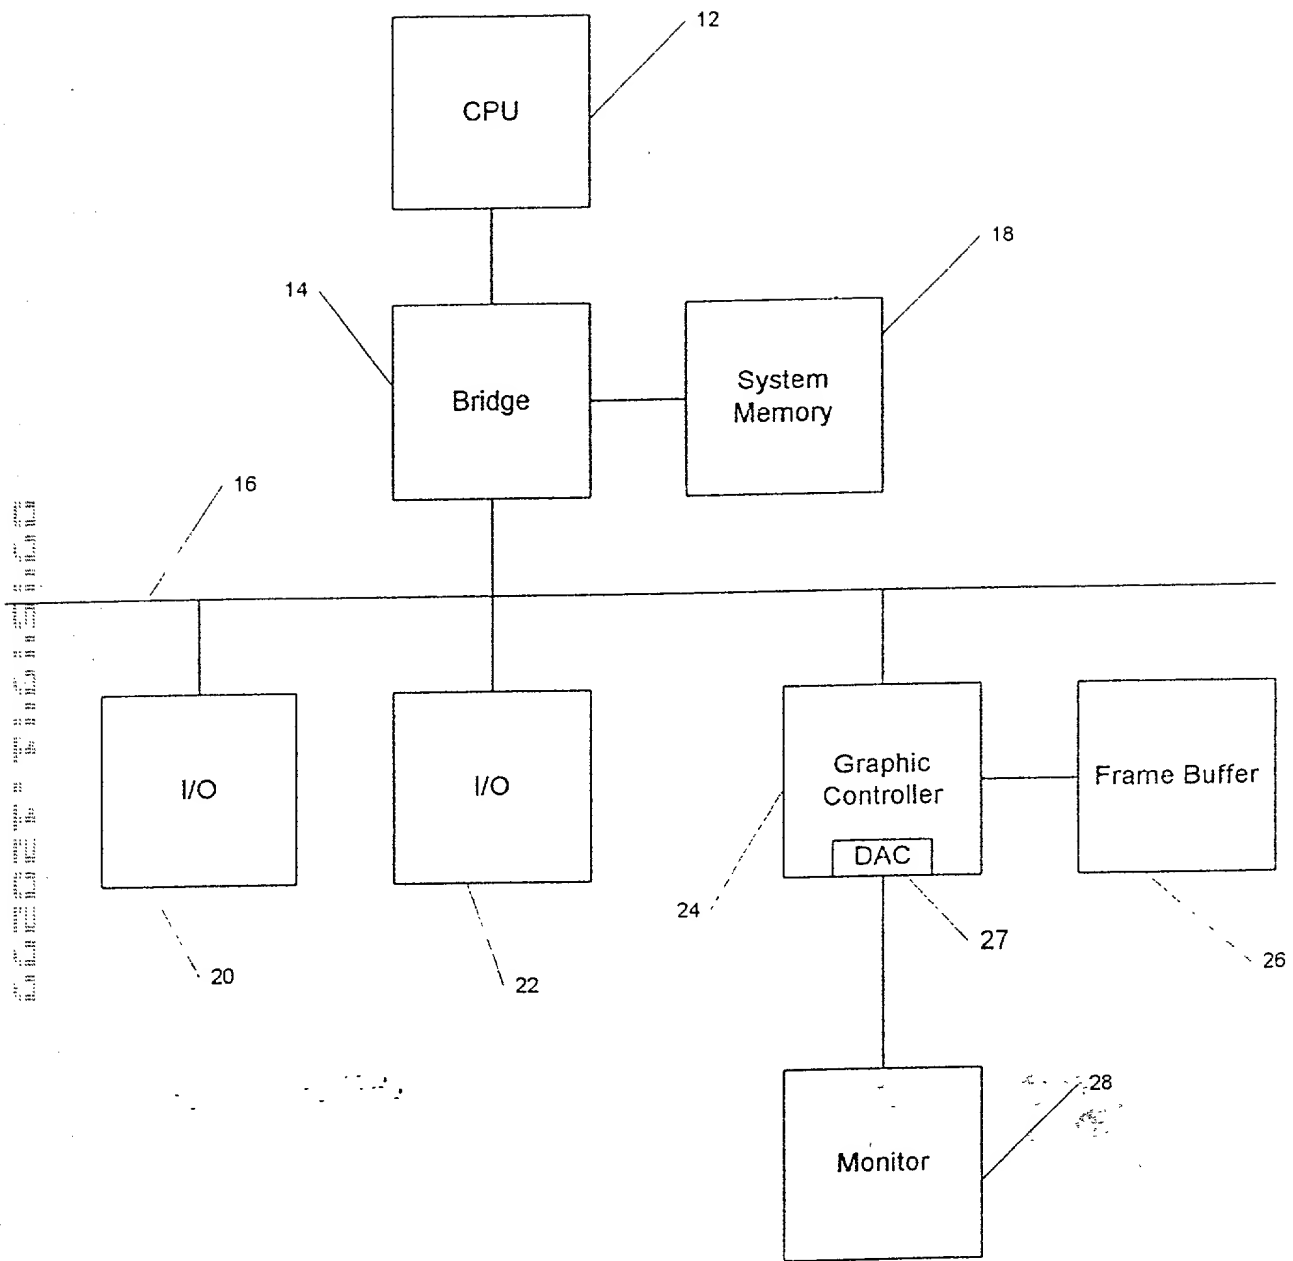

2 (c1) calculating the time required to fill the FIFO buffer;

3 (c2) determining if the FIFO buffer is below a predetermined amount based
4 upon the time required to fill the buffer; and

5 (c3) preventing the FIFO buffer from filling if the FIFO buffer is above the
6 predetermined amount.

ABSTRACT

A system and method for providing a command stream on a chip or in a computer system is disclosed. The system comprises a central processing unit (CPU), a controller coupled to the CPU and a memory coupled to the controller. The controller manages the memory. The system and method also includes a storage element coupled to the memory, the storage element being accessible by the CPU via the controller. The system and method in accordance with the present invention allows the controller to receive commands from the CPU and to manage the storage element, typically a first in first out (FIFO) buffer, and incorporates the storage element as part of the memory. In so doing, the system performance is significantly improved by providing a virtual FIFO buffer such that the CPU sees a FIFO buffer with a size equal to the size of the memory. The bandwidth of the bus between the controller and the memory is typically greater than that of the system bus. Hence the performance of the overall system is significantly improved. In addition, since the controller is the only device that has access to the memory, the bandwidth of the bus associated therewith is not divided between two devices. Further, since the controller is managing the storage element, the overhead considerations that related to managing the read and write pointers of the storage element by the CPU are eliminated. Finally, a technique in accordance with the present invention is provided such that the controller determines whether the storage element must be emptied, rather than requiring the CPU to perform this function. Through these features, a command stream can be provided efficiently on a chip or in a computer system.

DECLARATION AND POWER OF ATTORNEY FOR UTILITY PATENT APPLICATION

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below, next to my name,

I believe that I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled

METHOD AND SYSTEM FOR PROVIDING A COMMAND STREAM IN A COMPUTER SYSTEM

the specification of which

X is attached hereto.

___ was filed on ___, and assigned Serial No.: 0 / ___.

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above. I do not know and do not believe that the same was ever known or used in the United States of America before my invention thereof, or patented or described in any printed publication in any country before my invention thereof or more than one year prior to this application, that the same was not in public use or on sale in the United States of America more than one year prior to this application, and said invention has not been patented or made the subject of an inventor's certificate issued before the date of this application in any country foreign to the United States of America on an application filed by me or my legal representatives or assigns more than twelve months prior to this application.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, Section 1.56 (a).

I hereby claim foreign priority benefits under Title 35, United States Code, Section 119, of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:
